The method outlined below was developed by S. M. King in 1959 to calculate the account value of an unredeemed account at the time of termination. In determining the initial account value, the present day rate of interest (usually 4% annually) must be used. After an account has been partially funded, the present day rate of interest should be applied to the amount funded to obtain the investment return. After termination, the unredeemed balance of the account is calculated as the unredeemed part of the account times the present value of that balance. Example: When a merchant's account with a PSSM processor is terminated, the account records are not available. Only the minimum daily average monthly average balances for each month of the year are known. The processor has been providing a partial ACH service to the merchant for only the last few months. When the merchant's ACH service is terminated, the total monthly average for the year can be calculated as follows: The minimum daily average monthly average balances can be calculated as follows: Finally, the present value of the total monthly average balance for the year can be calculated as follows: If the unredeemed balance is \$1,500, then the present value of that balance (equivalent to the accrual
