Summary: Openness gives us a chance to connect to one another, to be open to learning from other people, to be open to learning about our own lives. At heart, we want to connect to each other because we have so much in common. Openness gives us a chance to connect to one another, to be open to learning from other people, to be open to learning about our own lives. At heart, we want to connect to each other because we have so much in common. Sometimes, we want to pretend that we are something else; sometimes, we even want to pretend that we don't have in common with other people. Sometimes, we want to defend our isolation. I have seen that happen. I have seen people fall in this trap. For example, some individuals who did well in school started to feel that they should be above anyone else, and they tried to pretend that they were something special. They made a point of telling everyone that they had access to "superior intelligence" because they had attended an elite school. They judged other people's achievements in the same way. They judged them as lesser because their accomplishments were not as impressive. For these people, they became concerned with "what people thought of them." The point was to feel better about themselves by pretending that they were superior to others. Their thinking became based on an idea that was false. That doesn't mean that they were wrong or that there was any basis in the truth for that idea. Their view was false. That is exactly the way that we think and experience life. We tend to assume

Though FMRP is well-known for its role in protein translation during development, we have recently demonstrated that FMRP inhibits neurofilament triplet gene expression in developing neurons and also in brains of aged patients with Fragile X syndrome, a disorder that causes a form of mental retardation. FMRP expression is modified during aging in humans, rats and fruit flies, and recently a mutation in the human FMR1 gene that causes Fragile X syndrome was linked to altered expression of FMRP. The long-term goal of these studies is to further define the role of FMRP in the nervous system, an ultimately necessary step towards understanding the basis of mental retardation in children with Fragile X syndrome and a broader range of mental disorders where FMRP may be important. Previous studies have demonstrated that FMRP binds to poly(A) RNA in vitro and represses translation of FMR1 mRNA, which encodes FMRP, but the role of FMRP in modulating the translation of native noncoding RNAs and neurofilament triplets in neurons is still unknown. To study this issue, we have cloned the neurofilament triplet genes, NTF2, NTF2b and NTF5M into mammalian expression vectors and placed them downstream of the strong cytomegalovirus (CMV) promoter to obtain stable overexpression of the neurofilament proteins. RNA immunoprecipitation studies demonstrate that FMRP binds to these neurofilament mRNAs. The FMRP binding sites on the neurofilament mRNAs are required for effective binding and repression. Studies of two of the FMRP binding sites suggest that FMRP specifically represses the translation of these mRNAs and not that of other mRNA targets of FMRP. We have also found that FMRP is required for the polyribosome association of the neurofilament triplet mRNAs. The role of FMRP in modulating neurofilament gene expression has several potential health implications, in particular in relation to the generation of axonal transport deficits in the Fragile X and other mental retardation syndromes.
