The MHC class I compartment consists of a membrane system derived from the endoplasmic reticulum (ER) that sequesters newly synthesized MHC class I molecules and facilitates their efficient transport to the cell surface. Depending on the type of aberrant protein, a subset of misfolded and/or partially assembled peptides remain in the ER. Here, we provide evidence that these aberrant peptides are efficiently targeted to the MHC class I compartment in a chaperone-independent manner. B cell lymphoma cell lines expressing a diverse array of naturally occurring and artificially generated class I molecules were tested for the ability to transfer the misfolded/partially assembled MHC class I heavy chains from the ER to the MHC class I compartment. The majority of these misfolded/partially assembled class I molecules were transferred to the MHC class I compartment. Transfer was dependent on the MHC class I heavy chain, as well as on the presence of accessory molecules from both the MHC class I and the tapasin classes. Importantly, class I molecules associated with the MHC class I compartment were functional at the cell surface. The transporter responsible for the transfer is not known. Nonetheless, the pathway described here may represent a key route for the transfer of misfolded proteins from the ER to the MHC class I compartment.Green chemistry and asymmetric transformations on a solid support. Supramolecular chemistry involving complexes between sugars and amino-acid derivatives has been reviewed and accounts have been given of their combination with various functional groups. A chapter on the highly versatile nucleophilic substitution reaction of the amine with disubstituted cyanate anions has been given in order to show the many possibilities open for incorporation of nucleophilic intermediates into these reactions. As a result of the unusually high stability of these complexes, many reactions of complex compounds have been suggested. These are mainly reactions of deprotonation of the 1cb139a0ed
